# 01-K Nearest Neighbors with Python

March 9, 2023

## 1 K Nearest Neighbors with Python

You've been given a classified data set from a company! They've hidden the feature column names but have given you the data and the target classes.

We'll try to use KNN to create a model that directly predicts a class for a new data point based off of the features.

Let's grab it and use it!

## 1.1 Import Libraries

```
[43]: import pandas as pd
import seaborn as sns
import matplotlib.pyplot as plt
import numpy as np
%matplotlib inline
```

## 1.2 Get the Data

Set index\_col=0 to use the first column as the index.

```
[74]: df = pd.read_csv("Classified Data",index_col=0)
[75]:
      df.head()
[75]:
              WTT
                        PTI
                                             SBI
                                                        LQE
                                                                  QWG
                                   EQW
                                                                             FDJ
         0.913917
                              0.567946
                                                  0.780862
                   1.162073
                                        0.755464
                                                             0.352608
                                                                       0.759697

                   1.522692
                              1.153093
                                                    1
      4 0.646691
                   1.463812
                              1.419167
                                                    1
```

#### 1.3 Standardize the Variables

Because the KNN classifier predicts the class of a given test observation by identifying the observations that are nearest to it, the scale of the variables matters. Any variables that are on a large scale will have a much larger effect on the distance between the observations, and hence on the KNN classifier, than variables that are on a small scale.

```
[78]: from sklearn.preprocessing import StandardScaler
      scaler = StandardScaler()
[79]:
[80]:
      scaler.fit(df.drop('TARGET CLASS',axis=1))
[80]: StandardScaler(copy=True, with_mean=True, with_std=True)
      scaled_features = scaler.transform(df.drop('TARGET CLASS',axis=1))
[82]: df feat = pd.DataFrame(scaled features,columns=df.columns[:-1])
      df feat.head()
[82]:
             WTT
                       PTI
                                  EQW
                                            SBI
                                                      LQE
                                                                          FDJ
                                                                QWG
      0 -0.123542  0.185907 -0.913431
                                      0.319629 -1.033637 -2.308375 -0.798951
      1 -1.084836 -0.430348 -1.025313
                                      0.625388 -0.444847 -1.152706 -1.129797
      2 -0.788702 0.339318 0.301511
                                      0.755873
                                                2.031693 -0.870156
                                                                     2.599818
      3 0.982841 1.060193 -0.621399
                                      0.625299 0.452820 -0.267220
                                                                     1.750208
      4 1.139275 -0.640392 -0.709819 -0.057175 0.822886 -0.936773 0.596782
             PJF
                       HQE
                                  NXJ
      0 -1.482368 -0.949719 -0.643314
      1 -0.202240 -1.828051 0.636759
      2 0.285707 -0.682494 -0.377850
      3 1.066491 1.241325 -1.026987
      4 -1.472352 1.040772 0.276510
     1.4 Train Test Split
[83]: from sklearn.model_selection import train_test_split
[84]: X_train, X_test, y_train, y_test = train_test_split(scaled_features,df['TARGET_L
```

#### 1.5 Using KNN

⇔CLASS'],

Remember that we are trying to come up with a model to predict whether someone will TARGET CLASS or not. We'll start with k=1.

test\_size=0.30)

```
[85]: from sklearn.neighbors import KNeighborsClassifier
```

#### 1.6 Predictions and Evaluations

Let's evaluate our KNN model!

```
[89]: from sklearn.metrics import classification_report,confusion_matrix
```

```
[90]: print(confusion_matrix(y_test,pred))
```

```
[[125 18]
[ 13 144]]
```

```
[91]: print(classification_report(y_test,pred))
```

support	f1-score	recall	precision	
143 157	0.89 0.90	0.87 0.92	0.91 0.89	0 1
300	0.90	0.90	0.90	avg / total

## 1.7 Choosing a K Value

Let's go ahead and use the elbow method to pick a good K Value:

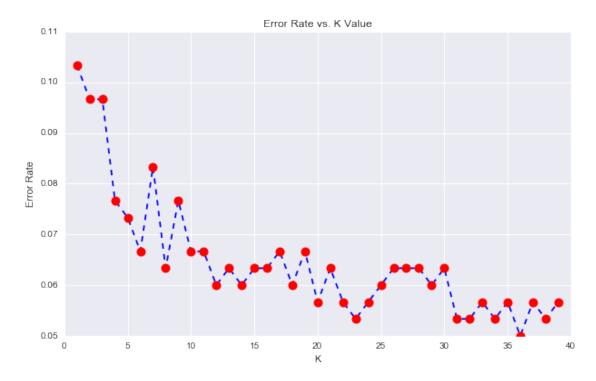

```
[98]: error_rate = []

# Will take some time
for i in range(1,40):

knn = KNeighborsClassifier(n_neighbors=i)
knn.fit(X_train,y_train)
pred_i = knn.predict(X_test)
error_rate.append(np.mean(pred_i != y_test))
```

```
plt.title('Error Rate vs. K Value')
plt.xlabel('K')
plt.ylabel('Error Rate')
```

### [99]: <matplotlib.text.Text at 0x11ca82ba8>

Here we can see that that after arouns K>23 the error rate just tends to hover around 0.06-0.05 Let's retrain the model with that and check the classification report!

```
[100]: # FIRST A QUICK COMPARISON TO OUR ORIGINAL K=1
knn = KNeighborsClassifier(n_neighbors=1)

knn.fit(X_train,y_train)
pred = knn.predict(X_test)

print('WITH K=1')
print('\n')
print(confusion_matrix(y_test,pred))
print('\n')
print(classification_report(y_test,pred))
```

WITH K=1

[[125 18]

[ 13 144]]

```
precision
                           recall f1-score
                                               support
          0
                   0.91
                             0.87
                                        0.89
                                                   143
                             0.92
                   0.89
                                        0.90
                                                   157
          1
avg / total
                   0.90
                             0.90
                                        0.90
                                                   300
```

```
[101]: # NOW WITH K=23
knn = KNeighborsClassifier(n_neighbors=23)

knn.fit(X_train,y_train)
pred = knn.predict(X_test)

print('WITH K=23')
print('\n')
print(confusion_matrix(y_test,pred))
print('\n')
print(classification_report(y_test,pred))
```

WITH K=23

[[132 11] [ 5 152]]

support	f1-score	recall	precision	
143	0.94	0.92	0.96	0
157	0.95	0.97	0.93	1
300	0.95	0.95	0.95	avg / total

## 2 Great job!

We were able to squeeze some more performance out of our model by tuning to a better K value!
